PS6 Report:

There are many potential issues that could arise from the shared sketch. For example, if multiple clients try to modify the same shape at the same time, it could lead to inconsistent states. Additionally, problems would arise if there is a delay in the sketches updating. This could cause a client to operate on an outdated version of the sketch. There is also the possibility of shape ID mismatches if users try to add shapes before getting confirmation from the server. The synchronized methods in Sketch prevent this last issue, as they ensure atomic updates to the shape list. That being said, the synchronized methods in Sketch don't resolve all problems as actions might still happen out of order due to network delays or simultaneous requests. Finally, we noticed that when we stacked several shapes on top of each other (typically at least 10), when we added new shapes, they would be added to the bottom layer of the sketch, making it impossible to see until you delete all the layers on top of it. We were unable to find the exact cause of this issue.
